Some NP-Hard Problems for the Simultaneous Coprimeness of Values of Linear Polynomials

By Starchak M.R, Kosovskii N.K & Kosovskaya T.M
St. Petersburg State University

Abstract- The algorithmic-time complexity of some problems connected with linear polynomials and coprimeness relation on natural numbers is under consideration in the paper.

We regard two easily stated problems. The first one is on the consistency in natural numbers from the interval of a linear coprimeness system. This problem is proved to be NP-complete. The second one is on the consistency in natural numbers of a linear coprimeness and discoprimeness system for polynomials with not greater than one non-zero coefficient. This problem is proved to be NP-hard.

Then the complexity of some existential theories of natural numbers with coprimeness is considered. These theories are in some sense intermediate between the existential Presburger arithmetic and the existential Presburger arithmetic with divisibility.

Keywords: NP, NP-completeness, NP-hardness, coprimeness of values of linear polynomials, simultaneous divisibility of linear polynomials, existential theories with coprimeness.

Abstract- The algorithmic-time complexity of some problems connected with linear polynomials and coprimeness relation on natural numbers is under consideration in the paper.

We regard two easily stated problems. The first one is on the consistency in natural numbers from the interval of a linear coprimeness system. This problem is proved to be NP-complete. The second one is on the consistency in natural numbers of a linear coprimeness and discordoprimeness system for polynomials with not greater than one non-zero coefficient. This problem is proved to be NP-hard.

Then the complexity of some existential theories of natural numbers with coprimeness is considered. These theories are in some sense intermediate between the existential Presburger arithmetic and the existential Presburger arithmetic with divisibility. In the form of corollaries from the theorems of the second section we prove NP-hardness of the decision problem for the existential theories of natural numbers for coprimeness with addition and coprimeness with successor function. In the conclusion section we give some remarks on the NP membership of the latter problem.

Keywords: NP, NP-completeness, NP-hardness, coprimeness of values of linear polynomials, simultaneous divisibility of linear polynomials, existential theories with coprimeness.

1. Introduction

The proof of NP-hardness of a certain computational problem gives us rather strong assurance of the absence of any polynomial-time algorithm for this problem. Hence, the existence of such proof gives us not only theoretical but also an important practical result for a working programmer. On the other hand, number-theoretical relations like divisibility or coprimeness of integers provides us one of the most natural languages for stating computational problems. We thus come to the study of the algorithmic-time complexity of the decision problems for various subclasses of arithmetic which are sometimes referred as weak arithmetics (see [16]). These reasons motivate the appearance of this paper.

The problem of integer linear programming (ILP) is well-known and one of the first to be proved NP-complete (see, [2] and [6], problem MP1). It can be regarded as a problem of consistency in non-negative integers of a system of linear equations with integer coefficients. In the sense of the weak arithmetics complexity this result can be interpreted as the NP-completeness of the decision problem for the existential Presburger Arithmetic \(\exists\Theta(\mathbb{N};+,\cdot,0,1)\) (abbreviated as \(\exists\PA\)). The decidability of Presburger Arithmetic is a classical result [15] and the complexity of its subclasses is studied rather extensively. For example, the paper [7] completes the classification of the time-complexity results corresponding fixed number of quantifier alternations and fixed maximum number of variables in each quantifier group. The lowest level of this subproblem hierarchy is just the famous H.W.Lenstra Jr. theorem [13] on the polynomial algorithm for ILP with a fixed number of variables. As was shown in [5] this result provides us with polynomial algorithms for various practical graph problems when we fix the value of some natural parameter of a given graph. In other words, there was proved the fixed-parameter tractability of these problems by rewriting each one as an instance of ILP. In this paper, we will prove NP-hardness of some problems from the extensions of \(\exists\PA\).

The time-complexity of \(\exists\PA\) extended with the divisibility relation \(x \mid y \iff \exists z (y = x \cdot z)\) was studied in [12, 14]. For this problem we will use the abbreviation \(\exists\PAD\). In non-deterministic polynomial time the problem is reducible to the consistency in non-negative integers of a system of linear divisibilities of the form

\[
\bigwedge_{i=1}^{m}(a_{i,0} + a_{i,1}x_1 + \ldots + a_{i,n}x_n \mid b_{i,0} + b_{i,1}x_1 + \ldots + b_{i,n}x_n).
\]  

L.Lipshitz in [14] proved that this problem is NP-complete for every fixed number of divisibilities \(m \geq 5\), whereas the general problem, as was shown in [12] by A.Lechner, J.Ouaknine and J.Worrell, is in \textsc{NEXPTIME}. The exact complexity of \(\exists\PAD\) remains an open problem, and the answer is of considerable interest as it will effect on the related problems of formal verification (see, for example, [3,11]). Some NP-complete problems with an arbitrary number of divisibilities but with restrictions on the values of the coefficients of linear polynomials are presented in [10].

One of the possible approaches to solve this problem is to establish complexity of some intermediate theories, that is, simultaneously extensions of \(\exists\PA\) and subclasses of \(\exists\PAD\). This question has not been studied apparently because of the common belief that \(\exists\PAD\) is in \textsc{NP} citing the paper [14]. This inaccuracy was firstly pointed at by the authors of [12]. For example, the paper [4] which considers existentially definable subsets...
of \(\exists\)PAD has the following sentences: “In [5] the algorithm of [4] is made into decision procedure of class \(\mathbf{NP}\). Hence each subdivisibility set is in the class \(\mathbf{NP}\). [...] Here we focus on other structural properties of these sets [...]”. In [8, 9] it was proved \(\mathbf{NP}\)-completeness for some kinds of systems of linear congruences \(\equiv\), incongruences \(\not\equiv\) and dis-equations \(\not=\), supplemented in some cases with geometric interpretations.

The object of consideration of this paper is the complexity of linear systems with coprimeness relation of the form

\[ \bigwedge_{i=1}^{m} (a_{i,0} + a_{i,1}x_{1} + \cdots + a_{i,n}x_{n} \perp b_{i,0} + b_{i,1}x_{1} + \cdots + b_{i,n}x_{n}). \]  

(2)

Here we use the notation \(x \perp y \Leftrightarrow \text{GCD}(x, y) = 1\), where \(\text{GCD}(x, y)\) is the greatest common divisor of non-negative integers \(x\) and \(y\), assuming \(-(0 \perp 0)\). The problem of consistency of the linear system (2) will be denoted as \(\text{SIMULTANEOUS COPRIMENESS OF LINEAR POLYNOMIALS (\(\perp\)LP)}\). We will state the \(\mathbf{NP}\)-completeness of a series of \(\perp\)LP problems with the values of the variables taken from an interval of non-negative integers. The relation \(x \in [a, b]\) is existentially definable using equality predicate. As a corollary, we get \(\exists\)PAD has the following sentences: “In [5] the algorithm of [4] is made into decision procedure of class \(\mathbf{NP}\). Hence each subdivisibility set is in the class \(\mathbf{NP}\). [...] Here we focus on other structural properties of these sets [...]”. In [8, 9] it was proved \(\mathbf{NP}\)-completeness for some kinds of systems of linear congruences \(\equiv\), incongruences \(\not\equiv\) and dis-equations \(\not=\), supplemented in some cases with geometric interpretations.

The problem of consistency of the linear system (2) will be denoted as \(\text{SIMULTANEOUS COPRIMENESS OF LINEAR POLYNOMIALS (\(\perp\)LP)}\). We will state the \(\mathbf{NP}\)-completeness of a series of \(\perp\)LP problems with the values of the variables taken from an interval of non-negative integers. The relation \(x \in [a, b]\) is existentially definable using equality predicate. As a corollary, we get \(\exists\)PAD has the following sentences: “In [5] the algorithm of [4] is made into decision procedure of class \(\mathbf{NP}\). Hence each subdivisibility set is in the class \(\mathbf{NP}\). [...] Here we focus on other structural properties of these sets [...]”. In [8, 9] it was proved \(\mathbf{NP}\)-completeness for some kinds of systems of linear congruences \(\equiv\), incongruences \(\not\equiv\) and dis-equations \(\not=\), supplemented in some cases with geometric interpretations.

We therefore can conclude that each \(\mathbf{NP}\)-hard problem mentioned above is in \(\textbf{NEXPTIME}\) complexity class. The simple definition of coprimeness in terms of divisibilities suggests that \(\exists \text{Th}(\mathbb{N}; \mathbb{S}, \perp)\) can be proved to be in the class \(\mathbf{NP}\) using the complexity analysis of the \(\exists\)PAD decision problem from [12]. This possibility is discussed in some concluding remarks after the \(\exists \text{Th}(\mathbb{N}; \mathbb{S}, \perp)\) \(\mathbf{NP}\)-hardness proof.

II. TWO \(\mathbf{NP}\)-HARD PROBLEMS FOR THE SIMULTANEOUS COPRIMENESS OF VALUES OF LINEAR POLYNOMIALS

By natural numbers we will further assume non-negative integers \(\mathbb{N} = \{0, 1, 2 \ldots \}\). As it was defined in the introduction, the relation \(x \perp y\) on natural numbers is true iff the greatest common divisor of \(x\) and \(y\) equals 1, thus we have \(- (0 \perp 0)\) and that for every \(x \in \mathbb{N}\) the formula \(x \perp 1\) is true. We can now define a series of problems, depending on the parameter \(k \in \mathbb{N}\).

**Simultaneous Coprimeness of Values of Linear Polynomials in the interval \([k, k+1]\) (\(\perp\)LP\([k, k+1]\)).**

**INPUT:** A set of \(m\) pairs of \((n+1)\)-dimensional vectors \((a_{0,i}, a_{1,i}, \ldots, a_{n,i}), (b_{0,i}, b_{1,i}, \ldots, b_{n,i})\) with natural entries for \(i \in [1, m]\).

**QUESTION:** Is the linear system

\[ \bigwedge_{i=1}^{m} (a_{i,0} + a_{i,1}x_{1} + \cdots + a_{i,n}x_{n} \perp b_{i,0} + b_{i,1}x_{1} + \cdots + b_{i,n}x_{n}) \]

consistent in natural numbers from the interval \([k, k+1]\)?

Let \(\perp \text{-LP}\([k, k+1]\) be a subproblem of \(\perp\)LP\([k, k+1]\) in which each pair of coprime linear polynomials contains one with exactly three non-zero coefficients and the other is a natural number.

**Theorem 1.** For every \(k \in \mathbb{N}\) the problem \(\perp \text{-LP}\([k, k+1]\) is \(\mathbf{NP}\)-complete.

**Proof.** That the problem is in the class \(\mathbf{NP}\) is obvious because every variable takes it values from the given interval of natural numbers.

To prove \(\mathbf{NP}\)-hardness of \(\perp\text{-LP}\([k, k+1]\) we will construct a polynomial reduction of \(\text{ONE-IN-THREE 3SAT}\) from [6] to our problem. The truth of exactly one literal in every clause can be expressed via expression

\[ 3k(3k+2) \perp x_{i,1} + x_{i,2} + x_{i,3}. \]

(6)

Logical constants true and false are encoded respectively by numbers \(k+1\) and \(k\). Every negated literal \(\neg x\) is substituted in the corresponding expression by a new variable \(x'\) and we add to the system three new expressions

\[ 3k(3k+2) \perp x + x' + u \]

\[ 3k(3k+2) \perp x + x' + v \]

\[ 3k(3k+2) \perp u + v + w, \]

(6)
which are simultaneously satisfiable only in the case $u=v=k$ and $w=k+1$. As the reduction is obviously polynomial, this completes the proof.

Corollary 1 from the Theorem 1. For every $k \in \mathbb{Z}$ the problem $\mathbb{LP}[k, k+1]$ is NP-complete.

Let us consider one related problem that is an extension of the previous one by the discoprimeness predicate. More formally, this problem is defined as follows.

**Simultaneous Coprimeness and Discoprimeness of Values of Linear Polynomials ($\mathbb{LP}$)**

**INPUT:** Two sets of $(m_1 + m_2)$ pairs of $(n+1)$-dimensional vectors: $\{(a_0, a_1, \ldots, a_{m_1}), (b_0, b_1, \ldots, b_{m_2})\}$ for $i \in [1, m_1]$ and $\{(a_0, a_1, \ldots, a_{m_1}), (b_0, b_1, \ldots, b_{m_2})\}$ for $j \in [1, m_2]$ with natural entries.

**QUESTION:** Is the system

$$\bigwedge_{i=1}^{m_1} (a_{i,0} + a_{i,1} x_1 + \ldots + a_{i,n} x_n \not\equiv b_{i,0} + b_{i,1} x_1 + \ldots + b_{i,n} x_n) \land \bigwedge_{j=1}^{m_2} (a_{j,0} + a_{j,1} x_1 + \ldots + a_{j,n} x_n \not\equiv b_{j,0} + b_{j,1} x_1 + \ldots + b_{j,n} x_n)$$

consistent in natural numbers?

Let $\mathbb{LP}$ be a subproblem of $\mathbb{LP}$ such that each linear polynomial has not greater than one non-zero coefficient and every coefficient and constant term is represented in unary.

**Theorem 2.** The problem $\mathbb{LP}$ is NP-hard.

**Proof.** To prove the NP-hardness of the problem, we will construct a polynomial reduction of a special case of SIMULTANEOUS INCONGRUENCES problem which is named “anti-Chinese remainder theorem” in [1]. It can be seen from the NP-completeness proof in [1], that every modulus in a system is square-free and its value is bounded polynomially in the number of the incongruences. This follows from the fact that in the polynomial reduction from 3SAT to SI, there were incongruences. This follows from the fact that in the NP completeness proof in [1], implicit gives us the NP-completeness of the following problem.

**Simultaneous Incongruences (SI) (Implicit in [1, Theorem 5.5.7])**

**INPUT:** A set of ordered pairs $(a_i, b_j)$ of positive integers, represented in unary, with $a_i \leq b_j$ and for every $i \in [1, m]$ the moduli $b_j$ are square-free.

**QUESTION:** Is there an integer $x$ such that

$$\bigwedge_{i=1}^{m} x \not\equiv a_i (\text{mod } b_j) \ ?$$

Every incongruence $x \not\equiv a_i (\text{mod } b_j)$ can be equivalently rewritten as a dis-divisibility: $-(b_j | x - a_i)$ or $-(b_j | x - (b_j - a_i))$. As every $b_j$ is square-free or, in other words, $b_j = \prod_{i=1}^{k} p_i$ for distinct primes $p_i$, by introducing new variables $u_i$, we can represent every dis-divisibility by the formula $-(u_i \land b_j) \land x \land (b_j - a_i)$. Thus, for every SI instance we have constructed the instance of $\mathbb{LP}$ of the form

$$\bigwedge_{i=1}^{m} (u_i \land x \land (b_j - a_i)) \land \bigwedge_{i=1}^{m} \neg(u_i \land b_j). \quad (7)$$

As this construction takes not greater than polynomial number of steps of a Turing machine, the problem $\mathbb{LP}$ is NP-hard.

Corollary 1 from the Theorem 2. The problem $\mathbb{LP}$ is NP-hard.

Note that in fact we have proved a stronger theorem as every coefficient in the constructed system (7) equals to one. This provides us with one subclass of $\exists \mathbb{N,S,\bot}$ formulas with NP-hard decision problem. We will state some corollaries from these two theorems, concerning complexity of decision problems for existential theories in the following section.

### III. SOME COROLLARIES ON THE TIME-COMPLEXITY OF THE DECISION PROBLEMS FOR EXISTENTIAL THEORIES WITH COPRIMENESS RELATION

The problems $\mathbb{LP}$ and $\mathbb{LP}$ can be interpreted as problems of validity in natural numbers for some classes of existentially closed formulas of the first-order language for coprimeness with addition or successor function and coprimeness with addition or successor function. We should only take care of the length of each formula that corresponds to an instance of $\mathbb{LP}$ or $\mathbb{LP}$. Let us first prove some lemmas on the definability of certain predicates in the theories with coprimeness.

**Lemma 1.** The relations $X=0$ and $X=1$ on natural numbers are existentially definable by successor $S_{x=x+1} = x$ and the coprimeness relation $x \perp y$.

**Proof.** These definitions are:

$$x = 1 \iff x \land \bot$$

and

$$x = 0 \iff 1 \land x \land \bot$$

**Lemma 2.** The unary relation $x = a$ and the binary relation $x = a \cdot y = y + y + \ldots + y$ (a times) for every natural number $a$ is existentially definable by addition function, equality and coprimeness relation. The length of the definition is bounded polynomially on the length of the binary representation of the number $a$.

**Proof.** Let $n = \lfloor \log(a) \rfloor$. As the relation $x_a = 1$ is definable, we can define $x_a = 2, x_a = 4, x_a = 8 \ldots x_a = 2^n$ by the formulas
\( x_i = x_{i-1} + x_{i-2} \), and finally \( x = \sum_{i=0}^{n} e_i \cdot x_i \), where \( e_0 \ldots e_n e_0 \) corresponds to the binary representation of the natural number \( a \). The relation \( X = a \) can be defined analogously by taking \( x_0 = x \).

**Corollary 2 from the Theorem 1.** Every instance of \( \bot L P[k, k+1] \) can be rewritten in polynomial time as a formula of \( \exists Th(\mathbb{N}; +, =, \bot) \).

**Proof.** Indeed, we only have to supplement the conjunction \( \bigwedge_{i=1}^{n} f_i(\bar{x}) \bot g_i(\bar{x}) \) from the instance of \( \bot L P[k, k+1] \) with the system of inequalities \( \bigwedge_{i=1}^{n} (k \leq x_i \land x_i \leq k+1) \). The predicate \( x \leq y \) is definable by the formula with equality: \( \exists u (x + u = y) \). From Lemma 2 it follows that every linear term \( f_i(\bar{x}) \) and \( g_i(\bar{x}) \) can be defined by a formula of polynomial size on the length of the binary representation of the integer coefficients. Thus, introducing \( n \) new variables we construct in polynomial time a formula from \( \exists Th(\mathbb{N}; +, =, \bot) \) which is true iff the given instance \( \bot L P[k, k+1] \) is solvable.

We thus have a series of \( \exists \)-NP-complete subproblems of the decision problem of \( \exists Th(\mathbb{N}; +, =, \bot) \) and \( \exists \)-NP-hardness of the general decision problem of this theory.

As it is not known whether the relation of equality is definable by addition and coprimeness, we have to independently consider the theory without equality. Let us define the problem \( \bot L P \) as the problem of consistency in natural numbers of a system of coprime values of linear polynomials. That is, unlike \( \bot L P[k, k+1] \), this problem does not have any restriction on the values of the variables. As the formulation of \( \bot L P \) is very similar to the one of \( \bot L P[k, k+1] \), we do not give it explicitly. The pairs of coprime polynomials in the proof given below will provide us with the \( \exists \)-NP-hardness proof for the decision problem of the corresponding theory without equality.

**Corollary 3 from the Theorem 1.** The problem \( \bot L P \) is \( \exists \)-NP-hard.

**Proof.** Consider the formulas from the proof of Theorem 1 in the case of \( k = 0 \). The system has form:

\[
\bigwedge_{i=1}^{n} (\bot x_{i-1} + x_{i-2} + x_{i-3})
\]

For every natural number, we have \( 0 \bot x \iff x = 1 \), therefore the restriction on the variables \( x_i \in [0, 1] \) is necessary satisfied. \( \exists \)-NP-hardness of \( \bot L P \) is proved by restriction to the \( \exists \)-NP-complete problem of the consistency in natural numbers of a system of the form (8).

As the relation \( X = 0 \) is definable by Lemma 1 in the theory \( \exists Th(\mathbb{N}; +, \bot) \), and the coefficients of linear polynomials from (8) all equal one, we immediately get the following corollary.

**Corollary 4 from the Theorem 1.** The decision problem of the theory \( \exists Th(\mathbb{N}; +, \bot) \) is \( \exists \)-NP-hard.

Note that we use in this corollary that the problem \( \bot L P \) remains \( \exists \)-NP-complete even in the case of the unary representation of the coefficients of polynomials in a system from its instance. Let us now consider formulas of the theory \( \exists Th(\mathbb{N}; S, \bot) \) with the successor function \( S x = x + 1 \) in place of addition. The formula (7) provides us with the following

**Corollary 2 from the Theorem 2.** The decision problem of the theory \( \exists Th(\mathbb{N}; S, \bot) \) is \( \exists \)-NP-hard.

**Proof.** To prove \( \exists \)-NP-hardness we can continue the polynomial reduction presented in the proof of Theorem 2. The relation \( X = 1 \) is definable in the considered theory, and therefore the unary relation \( \neg(X \bot \alpha \gamma) \) is also definable for every positive integer \( a \). As every natural number from the formula (7) is represented in unary, each polynomial \( a + x \) can be rewritten in the form \( S S \ldots S x \). By taking existential closure of every formula of the form (7) we define some formula from \( \exists Th(\mathbb{N}; S, \bot) \). This concludes the polynomial reduction of \( S I \) to the decision problem of \( \exists Th(\mathbb{N}; S, \bot) \).

A natural question is whether the decision problems considered above are in fact \( \exists \)-NP-complete. As every formula of these theories can be rewritten as a \( \exists \)-PAD formula, one can go through the complexity analysis of the \( \exists \)-PAD decision procedure from [12] for some restricted class of formulas. In conclusion, we will give some remarks corresponding \( \exists \)-NP membership of the decision problem for \( \exists Th(\mathbb{N}; S, \bot) \) formulas.

**IV. Conclusion**

Two easily formulated number-theoretic problems for coprimeness relation on natural numbers were defined in the first section. The problem of consistency of a coprimeness system of the form (2) was shown \( \exists \)-NP-complete on every interval \([k, k+1]\) of natural numbers. The related problem of consistency in natural numbers of a coprimeness and discoprimeness system of the form (3) was proved \( \exists \)-NP-hard when the linear polynomials have not greater than one non-zero coefficient.

We then derive some corollaries from these two theorems. There was established \( \exists \)-NP-hardness of the existential theories of natural numbers for coprimeness with addition \( \exists Th(\mathbb{N}; +, \bot) \) and for coprimeness with successor function \( \exists Th(\mathbb{N}; S, \bot) \). These problems naturally arise in such fields of computer science as formal verification or cryptography.

It could be an interesting problem to determine whether if \( \exists Th(\mathbb{N}; S, \bot) \) is in \( \exists \)-NP and the same question in
the case of every term from this theory of the form \( s_1 s_2 \ldots s_n x \) written on the tape of a Turing machine as the string \( a + x \) for the integer \( a \) represented in binary. Introducing new variables \( u_i \) and \( v_i \) while rewriting every coprimeness formula in the form of divisibility formula using the formulas (4), we get a 3PAD instance of rather convenient for the subsequent complexity analysis form. Every linear polynomial has form \( a + x \), and the formula is already increasing (in the sense of [12]) with respect to the total ordering \( 0 \leq v_1 \leq \ldots \leq v_r \leq x_1 \leq \ldots \leq x_s \leq u_1 \leq \ldots \leq u_t \) on the variables. An attempt to apply the 3PAD decision procedure from [12] on such restricted class of divisibility formulas to get an NP upper bound could be the subject of the subsequent research.
