Implementing a Search Engine for Bangladeshi E-Commerce Product

By Md. Mijanur Rahman, Razia Sultana Rupa & Hasan Mahmud Tuhin

Abstract- This project is concern with the practical implementation of Information Retrieval, where the main focus is on the algorithmic challenges in efficiently representing large data sets while supporting fast searches in the Web. The application was developed by using a system approach where analysis, design and development were carried out by the incremental model. The main aim of this work to introduce an efficient Information Retrieval System for Bangladeshi Ecommerce Product Search Engine. This search engine base on the technology of public search engine and is built specific for the structure of Bangladesh E-commerce Search Engine. The system provides the relevant searching results from Bangladeshi web domains. The proposed system has been designed and developed using Python programing language tools and methods.

Keywords: e-search engine, indexing process, information retrieval, query process, web crawler.

GJCST-B Classification: K.4.4 , J.1
Implementing a Search Engine for Bangladeshi E-Commerce Product

Abstract-This project is concerned with the practical implementation of Information Retrieval, where the main focus is on the algorithmic challenges in efficiently representing large data sets while supporting fast searches in the Web. The application was developed by using a system approach where analysis, design and development were carried out by the incremental model. The main aim of this work is to introduce an efficient Information Retrieval System for Bangladeshi E-commerce Product Search Engine. This search engine bases on the technology of public search engine and is built specific for the structure of Bangladeshi E-commerce Search Engine. The system provides the relevant searching results from Bangladeshi web domains. The proposed system has been designed and developed using Python programming language tools and methods.

Keywords: e-search engine, indexing process, information retrieval, query process, web crawler.

I. Introduction

Generally, people use search engine for one of the three things, such as, research, shopping and entertainment [1]. For example, Amazon, Yahoo! Shopping, Google product search etc. handles all of the purchasing, shipping and ordering info. People also look up things like videos, movies, games, social networking sites etc. There are many E-commerce sites in Bangladesh, they are increasing in size and number day by day [2]. There is no special search engine to search for product all over these sites. Though the size of information is rapidly increasing in this field, we need an efficient Information Retrieval System to make better use. So, a new Information Retrieval System named as “Bangladesh E-commerce Product Search Engine” is introduced in this project. The proposed system can help to find best relevant data from those sites within a second.

II. E-search Engine

The search engine is a software system [3] that compares queries to documents and produces ranked result lists of the documents. Search engine must be able to capture, or crawl, many terabytes of data, and then provide sub second response times to millions of queries submitted every day. This software is a program that search documents for specified keywords given through the E-commerce sites [4] and returns a list of the documents where the keywords were found. Typically, Web search engines work by sending out a spider to fetch as many documents as possible [5]. Another program, called an indexer [6] then reads these documents and creates an index based on the words contained in each document. Each search engine uses a proprietary algorithm to create its indices such that, ideally, only meaningful results are returned for each query. The search engine activities and the core information retrieval issues are shown in Figure-1.

The architecture of e-Search Engine is designed to ensure that a system will satisfy the application requirements of search engine are effectiveness (quality), means it able to (i) effectiveness (quality), that is we want to retrieve the most relevant set of documents possible for a query; and (ii) efficiency (speed), that is, we want to process queries from users as quickly as possible [7].
III. Functions of E-search Engine

Search engine components support two major functions, such as, indexing process and the query process [8]. The indexing process builds the structures that enable searching. The query process uses those structures and a person’s query to produce a ranked list of documents.

a) Indexing Process

Indexing process involves acquiring data from various sources. Indexing includes several major components, such as, text acquisition, text transformation, and index creation, as shown in Figure-2 [8].

The text acquisition component is used to identify and make available the documents that will be searched. Text acquisition will more often require building a collection by crawling or scanning the sources of information. Then the documents to the next component data store, which contains the text and metadata for all the documents. The text transformation component transforms documents into index terms or features and then the documents are stored in index and used for searching. Also, the index creation component takes the output of the text transformation component and creates the indexes or data structures that enable fast searching.

Figure 2: The indexing process

b) Query Process

This part process user query and find document using index and rank the document for the efficiency of search engine. The proposed search engine involves BM25 ranking algorithm [9] for calculating the rank of a document, shown in Figure-3. The major components of the query processing are user interaction, ranking and evaluation, as shown in Figure-4 [8].

The user interaction component provides the interface between the person doing the searching and the search engine. The main task is to accept user’s query and transform it into index terms and then to take the ranked list of documents from the search engine and organize it into the results shown to the user. The ranking component takes the transformed query from the user interaction component and generates a ranked list of documents using scores based or a retrieval model [9]. The task of evaluation component is to measure and monitor effectiveness and efficiency. An important part of that is to record and analyze user behavior using log data. Evaluation is primarily an offline activity, but it is a critical part of any search application.
**Rank Calculation**
Given a query $Q$ containing keywords $(q_1, q_2, q_3, ..., q_n)$.

The BM25 score of a document is given by

$$score(D, Q) = \sum_{i=1}^{n} IDF(q_i) \times \frac{f(q_i, D). (k_1 + 1)}{f(q_i, D) + k_1(1 - b + \frac{b|D|}{avdl})}$$

Where,

- $f(q_i, D) = is q_i is term frequency$
- $|D|$ is the length of the document
- $k_1$ and $b$ are free parameters chosen in absence of an advanced optimization
- $IDF(q_i)$ is given by
  $$IDF(q_i) = \log \frac{N - n(q_i) + 0.5}{n(q_i + 0.5)}$$

Where,

- $N = total number of documents in the collections$
- $n(q_i) = number of documents containing q_i$

**IV. The Web and Web Crawler**

Web crawler, database and the search interface are the major component [10] of a search engine that actually makes search engine to work in the Web. The structure of the Web is shown in Figure-5 which include the crawler, the parser and the downloader [11]. Search engines are programs that search documents for specified keywords and returns a list of the document. The web crawler program is to search for the information in the database. Once web crawler finds the pages, the search engine then shows the relevant web pages as a result. A Web crawler is an Internet bot which systematically browses the WWW [12]. A web crawler is designed to follow the links on web pages to discover and download new pages. Web crawlers are also known as ants, automatic indexers, bots, spiders, web robots, and worms. The crawler is adapted to discover and update all documents related to a company’s operation.
The design methodology of the proposed system is described by the data flow diagram, as shown in Figure 6. To develop the proposed system, several methods have been implemented in Python programs, such as, Downloader, Parser, Crawl, Tokenize, Build_Index, Query_Transformation, Scoring_Algorithm, etc.

The Downloader(url, retry) method is used to download resource from given URL. The Parser (HTML, ALLOWED_DOMAIN<DEPTH) method parses resource returned by download. The Crawl(allowed_domain, depth) method uses other two methods Parser and Downloader for crawling. The Tokenize (data) method performs text transformation and makes them ready to build index. The Build_index(data) method builds inverted index from transformed data. The Query_transformation(query) method is used to transform user query into tokens so that we can use them with inverted index. The scoring_algorithm(query) transforms user query so that to make them compatible to indexed data. Also a user friendly interface (see Figure 7) has been developed to interact with the proposed that the users can easily access the system.

**V. Proposed System Design and Implementation**

The design methodology of the proposed system is described by the data flow diagram, as shown in Figure 6. To develop the proposed system, several methods have been implemented in Python programs, such as, Downloader, Parser, Crawl, Tokenize, Build_Index, Query_Transformation, Scoring_Algorithm, etc.

The Downloader(url, retry) method is used to download resource from given URL. The Parser (HTML, ALLOWED_DOMAIN<DEPTH) method parses resource returned by download. The Crawl(allowed_domain, depth) method uses other two methods Parser and Downloader for crawling. The Tokenize (data) method performs text transformation and makes them ready to build index. The Build_index(data) method builds inverted index from transformed data. The Query_transformation(query) method is used to transform user query into tokens so that we can use them with inverted index. The scoring_algorithm(query) transforms user query so that to make them compatible to indexed data. Also a user friendly interface (see Figure 7) has been developed to interact with the proposed that the users can easily access the system.
VI. Results and Conclusion

Total 2228 documents are indexed and there has 12858 Bangla keywords used in the proposed system. The indexed documents are retrieved from following Bangladeshi domains: rang-bd.com (2), rokomari.com (790), aarong.com (278), oo.com.bd (2), sohojshopping.com (215), priyoshop.com (2), daraz.com.bd (441), bdhaat.com (398), kaymu.com.bd (2), bagdoom.com (2), hutbazar.com (61), fortunabangladesh.com (46), ajkerdeal.com (2). The outcomes of the proposed system is shown in Figure-7.
The main aim of this work is to introduce an efficient Information Retrieval System for Bangladesh E-commerce Product Search Engine, so that the proposed system can help to find best relevant data from those sites within a seconds. Though small amount of document and poor text transformation technique search result are not efficient as we expected. The web crawler could not fetch many information correctly, because E-commerce sites use a lots amount of JavaScript, and to get that data the system need to interact with some JavaScript event. This may be improved by using an intelligent web crawler and better text transformation technique. Also spell checking and making query suggestions may be employed further.
