Oedematous Skin Disease (OSD) Transmission among Buffaloes

By Arafa M. I., Hamouda S. M., Rateb H. Z., Abdel-Hafeez M. M. & Aamer A. A.
Animal Health Research Institute (AHRI)

Abstract- During buffaloe OSD spread in a village affiliating to Assiut Governorate-Egypt, 44 buffaloe cows hosted and owned sporadically were subjected to the study. From 43 buffaloe cows (had closed lesions either edematous or nodular) and a buffaloe cow (had open ulcerative lesion), Corynebacterium pseudotuberculosis equi (C. ps. equi) as 72% and Corynebacterium pseudotuberculosis ovis (C. ps. ovis) as 28% were isolated and identified. Blood sucking insects hosted on the infected buffaloe cows (no. 22) louse fly(Hippobosca equine) and 20 Haematopinus eurysternus lice were included during the study where both C. ps. equi and C. ps. ovis were isolated from Hippobosca equina (H. equina) but failed to isolate any biovar of C. ps from Haematopinus eurysternus lice (H. eur.). Moreover, C. ps. equi was isolated from two H equina pupae – lab deposited – as well as a H equina second generation fly concluding that there is endosymbiosis nature of C.ps limited only to H. equina fly which can transmit C.ps vertically.

Keywords: buffaloes, oedematous skin disease, corynebacterium pseudotuberculosis, hippobosca equina.

I. Introduction

II. Material & Methods

a) Insects sampling

Through a private clinic in Fayama village (15 Km. east north from Assiut city, Assiut Governorate) the study conducted on 44 buffaloe cows - owned and hosted sporadically - suffering from OSD ectoparasite infested, where 70 adult blood sucking insects (40 H. equina flies & 30 H. eur. lice) were gathered. 22 H. equina flies as well as 20 H. eurysternus lice were used for bacteriological examination and the rest were used in parasitological investigation.

The insects were collected directly using sterile forceps from infected buffalo or donkeys hosted together. They were kept into plastic sacs or wide-naked bottles for laboratory examination where they taxonomically identified (Soulsby, 1982 and Kettle, 1984). 22 H. equina flies as well as 20 H. eurysternus lice were used for bacteriological examination and the rest were used in parasitological investigation.

b) Lab reared H. equina flies

18 flies were still alive for 24 hours where some of them deposited their larvae (Full mature larvae) inside the collected sacs until larvae pupated. The achieved pupae were incubated at room temperature in plastic sand containers covered with a piece of gauze until giving adult fly (Baraka, 1983). These different stages were photomicrograph.

c) Bacteriological examination

Bacteriological examination was conducted with 22 flies gathered in sterile plastic sacs from infested animals (17 affected buffaloes, 4 cattle and a donkey hosted together). In addition to two pupae (lab deposited) and one laboratory developed fly (second generation) as well as 20 H. eur. lice for bacterial existence as follows:

1. Fly was inoculated as it is into a sterile nutrient broth tube for bacterial isolation from body surface, legs and external mouth parts contamination (EBS).
2. The forceps caught fly was washed several times using sterile distilled water to rinse the rest of external contamination.
3. The washed fly was crushed, destructed and macerated into another nutrient broth tube for isolation of gut bacterial content (IBC).
4. The above mentioned three procedures were performed on lice (20) from only affected buffaloes.
5. To obtain their external (EBS) and internal (IBC) bacterial contents.
6. From the laboratory deposited pupae, 2 were burst into nutrient broth to isolate their bacterial contents.

d) Bacteriological examination

The above mentioned test tubes were overnight incubated aerobically at 37ºC, and then were streaked onto 10% sheep blood agar (24 - 48 h). Growing colonies were purified and identified morphologically by Gram's stain. Biochemically tested for motility, glucose and maltose fermentation, catalase activity and nitrate reduction were adopted (Quinn et. al., 2011).

III. Results

Parasitologically, all diseased buffaloes were infested with dark leathery flies identified as H. equina.

Adult flies were more abundant on stabled diseased animals. They mainly aggregated under the tail, on the udder, around genitalia and inner aspect of thighs. Flies were dark brown in color measuring 9 x 4.5-10.5 x 5.0 mm. Their abdominal segmentation was indistinct. Wings were longer than body length while wing veins crowded towards the anterior border. Flies had three pair of feet is provided with strong claws (fig: 1). Five diseased buffaloes were infested also with sucking lice identified as H. eur. having a relatively short head and broad thorax and abdomen measuring about 4 x 2 - 5 x 2.5 mm (fig: 2).

Out of 8 full mature H. equina larvae creamy in color, oval shape measuring 1.5 x 2.5 mm provided with a small spine posteriorly, 5 pupated (6-10) hours (fig: 3). Pupation period was 30 days where the pupa is broadly oval with two round postero-lateral spiracular lobes producing a full mature fly. Pupa was yellowish in color measuring 4.0 x 2.5-4.5 x 3 mm. It was soft and covered with sticky layer but at 24 hours later, it became dark red to black in color and quit hard (fig: 4).

Bacteriological investigation results are tabulated in tables (1 & 2).

pathogens from the infected subcutaneous tissues, the
showed closed (edematous or nodular) lesions avoiding
present study, out of 44 affected buffaloe cows, 43
remained for long periods on their hosts and are not easily
disturbed in addition it has very long mouthparts are
adapted for piercing thick skin (Selim 2001). In the
infestation (Selim 2001,) (hairless areas as axilla and
groin (Syame et al. 2008), inner aspect of limbs and
under tail) (Selim 2001,).

Basing on nitrate reduction test, the
identification of bacterial isolates all over the study
revealed that both C. ps. biovars were recovered as C.
ps. Equi and C. ps. Ovis represented 72 & 28 %, while
from buffaloe lesions resembled 68.5 & 31.5% respectively (Table 1). Some studies stated that OSD is
associated only with C. ps. Equi (Selim 2001, Selim et al.
2016, Viana et al. 2017), while others detected both C.
ps. biovars as causative agents in cattle ulcerative lymphangitis (Yeruham et al., 1997 Yeruham et al.,
2003, Yeruham et al.). C. ps. transmission among
buffaloe is a conflicting issue since some studies
concluded that it is only mechanical by insects (Khalel et
al., 1995; Zaghawa and El-Gharib, 1996; Ali and
Zaitoun, 1999, Doherr et al., 1999) mainly blood sucking
insects - as mentioned above - (Khater et al., Selim
2001., Barakat et al. 1985 Soares et al. 2013) as having a
protrusion that can pierce the thick buffalo skin. These
conditions coordinates with H. equina features which
remain for long periods on their hosts and are not easily
disturbed in addition it has very long mouthparts are
adapted for piercing thick skin (Selim 2001). In the
present study, out of 44 affected buffaloe cows, 43
showed closed (edematous or nodular) lesions avoiding
suggestion of mechanical transmission unless through
piercing the whole skin thickness to contract the
pathogens from the infected subcutaneous tissues, the
condition presented only related to H. equine (Selim
2001) when be with contaminated piercing mouth parts.

IV. Discussion

OSD appears mainly among buffaloes and occasionally cattle in Egypt confined to Lower Egypt as a result of the suitable climatic conditions (Selim 2001, Mohamad and Reda 2015), especially during late spring and early summer (Yeruham et al 1997, Mohamad and Reda 2015, Sokø and Michalski 2015) correlating with H. equina breeding season (Barakat et al. 1985, Selim 2001, Syame et al 2008, Sokø and Michalski 2015) and lesions are associated with its predilection seats of infestation (Selim 2001,) (hairless areas as axilla and groin (Syame et al. 2008), inner aspect of limbs and under tail) (Selim 2001,).

Even, from the blood sucking H. eur. lice with piercing mouth part just a vessel feeder could not reach to the infected subcutaneous tissue (Roberts and Janovy 1996), the present study failed to isolate any C. ps. strain from H. eurysternus lice infesting the infected buffaloes in different locations (Table 1) suggesting that it cannot act as a mechanical or biological vector for C. ps. These finding concluded that not any blood sucking insect has role in transmission, but among blood sucking insects, it is associated with H. equine (Selim 2001, Ghoneim et al. 2001). Musca domestica (house flies) with mouth part adapted only for a liquid diet not to pierce host skin (Kettle 1990) have been confirmed as potential vectors for C. ps. equi among horse (Yeruham et al., 2003 and Spier et al., 2004) or cattle (Abou-Zaïd and Hammam, 1994; Sayed, 2001) with ulcerative lesions mechanically. C. ps. equi survival inside the fly’s gut experimentally - on feeding house flies on C. ps. equi broth - revealed that the pathogen presented in fly droppings for only up to 4 h and in saliva up to 3 h post infection (Yeruham et al 1996). Some studies investigated the existence of the C. ps.equi inside Musca domestica by PCR detection of its phospholipase D (PLD) exotoxin gene (Spier et al 2004, Barba 2015) with great disadvantage that detection of PLD did not inform about the viability of pathogens. In the present study bacterial isolation of C. ps. biovar equi from all H. equine life stages (adult flies, their pupae either gathered or lab deposited as well as the second generation flies) viable up to 30 days post collection ascertained that there is endosymbiosis nature of C.ps. limited only to H. equina fly which can transmit C.ps. vertically.

The study concluded that both C. ps. biovars (equi & ovis) could be isolated from buffaloe OSD lesions. Its transmission is associated only to H. equina fly, the mechanical and biological vector for buffaloe OSD, since it is proved that there is endosymbiosis nature of C.ps. limited only to H. equina fly which can transmit C.ps. vertically.
